ABSTRACT

In a liquid crystal display device which is capable of performing both of a transmissive display and a reflective display using a transmissive type liquid crystal display panel, 5 the influence attributed to a shade as viewed from the oblique direction can be reduced so that the favorable visibility can be ensured. In a liquid crystal display device including a transmissive type liquid crystal display panel which sandwiches a liquid crystal layer between a pair of substrates and a backlight 10 which is arranged at a back face of the liquid crystal display panel and has a light source and a reflector and is capable of performing a transmissive display which uses light from the light source and a reflective display which uses an external light incident from a front face side of the liquid crystal display 15 panel by reflecting the external light on the reflector, at least two or more light diffusion layers are arranged between the back-face-side substrate out of the pair of substrates and the reflector of the backlight.
